Here, look for the Power field which will tell you how much power the device is capable of withdrawing. It's possible that a port is capable of outputting more power than a device is capable of withdrawing. It isn't easy to identify which USB port is named what in the system. Likewise, not many USB devices except phones, can be identified by their names simply because they don't have one. With newer systems, you'd be hard put to find a USB port that isn't USB 3.0; however, you will still have a composite port which likely doubles as a charging port, and is what you should use to connect a USB 2.0. The port's power output will tell you how much power the port can supply whereas the device's power value will tell you how much power the device can withdraw from the port.
